Optimization in Machine Learning

Bayesian Optimization: Posterior Uncertainty and Acquisition Functions II

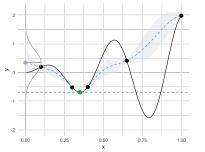

Learning goals

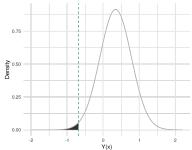

- Probability of improvement
- Expected improvement

Goal: Find $\mathbf{x}^{[t+1]}$ that maximizes the **Probability of Improvement** (PI):

$$a_{\mathsf{Pl}}(\mathbf{x}) = \mathbb{P}(Y(\mathbf{x}) < f_{\mathsf{min}}) = \Phi\left(\frac{f_{\mathsf{min}} - \hat{f}(\mathbf{x})}{\hat{s}(\mathbf{x})}\right)$$

where $\Phi(\cdot)$ is the standard normal cdf (assuming Gaussian posterior)

Left: The green vertical line represents f_{min} . **Right:** $a_{PI}(\mathbf{x})$ is given by the black area.

Goal: Find $\mathbf{x}^{[t+1]}$ that maximizes the **Probability of Improvement** (PI):

$$a_{\mathsf{Pl}}(\mathbf{x}) = \mathbb{P}(Y(\mathbf{x}) < f_{\mathsf{min}}) = \Phi\left(\frac{f_{\mathsf{min}} - \hat{f}(\mathbf{x})}{\hat{s}(\mathbf{x})}\right)$$

where $\Phi(\cdot)$ is the standard normal cdf (assuming Gaussian posterior)

Note: $a_{PI}(\mathbf{x}) = 0$ for design points \mathbf{x} , since

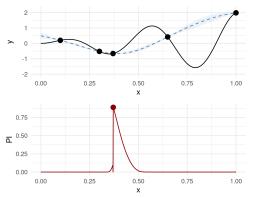

- $\bullet \hat{s}(\mathbf{x}) = 0,$
 - $\hat{f}(\mathbf{x}) = f(\mathbf{x}) \ge f_{\min}$ \Leftrightarrow $f_{\min} \hat{f}(\mathbf{x}) \le 0$.

Therefore:

$$\Phi\left(\frac{f_{\min}-\hat{f}(\mathbf{x})}{\hat{s}(\mathbf{x})}\right)=\Phi\left(-\infty\right)=0$$

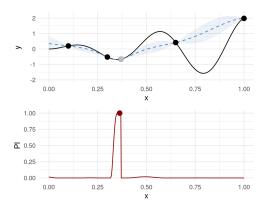

The PI does not take the size of the improvement into account Often it will propose points close to the current f_{min}

We use the PI (red line) to propose the next point ...

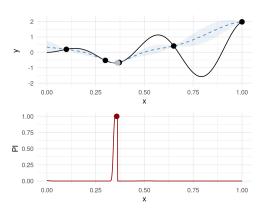

The red point depicts arg $\max_{\mathbf{x} \in \mathcal{S}} a_{PI}(\mathbf{x})$

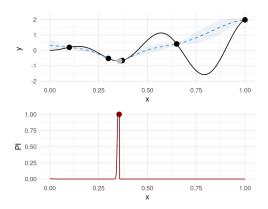

... evaluate that point, refit the SM and propose the next point

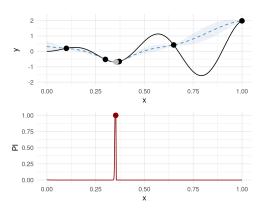

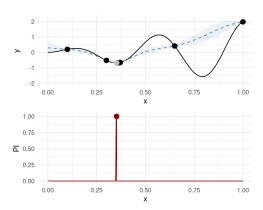

(grey point = prev point from last iter)

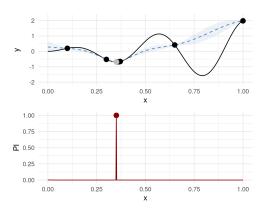

In our example, using the PI results in spending plenty of time optimizing the local optimum ...

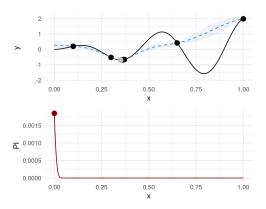

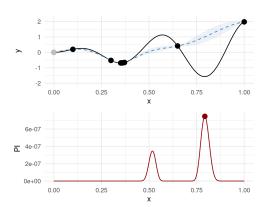

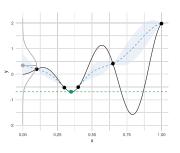

... eventually, we explore other regions ...

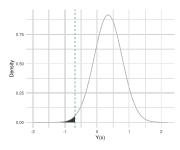

Goal: Propose $\mathbf{x}^{[t+1]}$ that maximizes the **Expected Improvement** (EI):

$$a_{\text{EI}}(\mathbf{x}) = \mathbb{E}(\max\{f_{\min} - Y(\mathbf{x}), 0\})$$

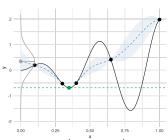

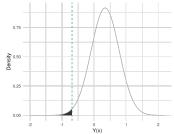

- We now take the expectation in the tail, instead of the prob as in PI.
- Improvement is always assumed ≥ 0 .

Goal: Propose $\mathbf{x}^{[t+1]}$ that maximizes the **Expected Improvement** (EI):

$$a_{\mathsf{EI}}(\mathbf{x}) = \mathbb{E}(\max\{f_{\mathsf{min}} - Y(\mathbf{x}), 0\})$$

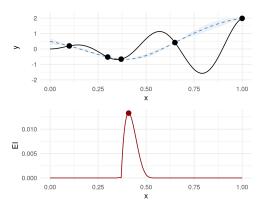

If $Y(\mathbf{x}) \sim \mathcal{N}\left(\hat{f}(\mathbf{x}), \hat{s}^2(\mathbf{x})\right)$, we can express the EI in closed-form as:

$$a_{\rm EI}(\mathbf{x}) = (f_{\rm min} - \hat{f}(\mathbf{x}))\Phi\Big(\frac{f_{\rm min} - \hat{f}(\mathbf{x})}{\hat{\mathbf{s}}(\mathbf{x})}\Big) + \hat{\mathbf{s}}(\mathbf{x})\phi\Big(\frac{f_{\rm min} - \hat{f}(\mathbf{x})}{\hat{\mathbf{s}}(\mathbf{x})}\Big),$$

• $a_{EI}(\mathbf{x}) = 0$ at design points \mathbf{x} :

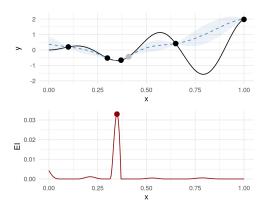

$$a_{\mathsf{EI}}(\mathbf{x}) = (f_{\mathsf{min}} - \hat{f}(\mathbf{x})) \underbrace{\Phi\left(\frac{f_{\mathsf{min}} - \hat{f}(\mathbf{x})}{\hat{s}(\mathbf{x})}\right)}_{=0. \text{ see PI}} + \underbrace{\hat{s}(\mathbf{x})}_{=0} \phi\left(\frac{f_{\mathsf{min}} - \hat{f}(\mathbf{x})}{\hat{s}(\mathbf{x})}\right)$$

We use the EI (red line) to propose the next point ...

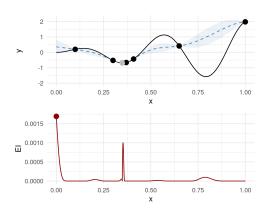

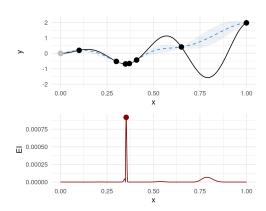

The red point depicts arg $\max_{\mathbf{x} \in \mathcal{S}} a_{EI}(\mathbf{x})$

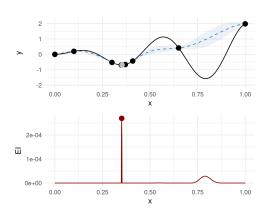

... evaluate that point, refit the SM and propose the next point

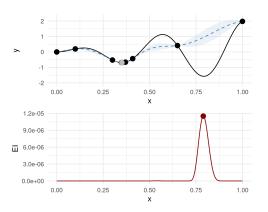

(grey point = prev point from last iter)

The EI is capable of exploration and quickly proposes promising points in areas we have not visited yet

Here, also a result of well-calibrated uncertainty $\hat{s}(\mathbf{x})$ of our GP.

DISCUSSION

- Under some mild conditions: BO with a GP as SM and EI is a global optimizer, i.e., convergence to the global (!) optimum is guaranteed given unlimited budget
- Cannot be proven for the PI or the LCB
- In theory, this suggests choosing the EI as ACQF
- In practice, LCB works quite well, and EI generates a very multi-modal landscape

Other ACQFs:

- Entropy based: Entropy search, predictive entropy search, max value entropy search
- Knowledge Gradient
- Thompson Sampling
- ...
