# **Optimization in Machine Learning**

# Mathematical Concepts: Quadratic forms II

#### Learning goals

- Geometry of quadratic forms
- Spectrum of Hessian

# PROPERTIES OF QUADRATIC FUNCTIONS

**Recall**: Quadratic form *q* 

- Univariate:  $q(x) = ax^2 + bx + c$
- Multivariate:  $q(\mathbf{x}) = \mathbf{x}^T \mathbf{A} \mathbf{x} + \mathbf{b}^T \mathbf{x} + c$

**General observation:** If  $q \ge 0$  ( $q \le 0$ ), q is convex (concave)

**Univariate function:** Second derivative is q''(x) = 2a

- $q''(x) \stackrel{(>)}{\geq} 0$ : q (strictly) convex.  $q''(x) \stackrel{(<)}{\leq} 0$ : q (strictly) concave.
- High (low) absolute values of q''(x): high (low) curvature

**Multivariate function:** Second derivative is H = 2A

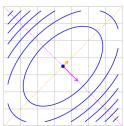

- Convexity/concavity of q depend on eigenvalues of H
- Let us look at an example of the form  $q(\mathbf{x}) = \mathbf{x}^T \mathbf{A} \mathbf{x}$

**Example:** 
$$\mathbf{A} = \begin{pmatrix} 2 & -1 \\ -1 & 2 \end{pmatrix} \implies \mathbf{H} = 2\mathbf{A} = \begin{pmatrix} 4 & -2 \\ -2 & 4 \end{pmatrix}$$

• Since **H** symmetric, eigendecomposition  $\mathbf{H} = \mathbf{V} \wedge \mathbf{V}^T$  with

$$\mathbf{V} = \begin{pmatrix} | & | \\ \mathbf{v}_{\text{max}} & \mathbf{v}_{\text{min}} \\ | & | \end{pmatrix} = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1 \\ -1 & 1 \end{pmatrix} \text{ orthogonal}$$

and 
$$\Lambda = \begin{pmatrix} \lambda_{\text{max}} & 0 \\ 0 & \lambda_{\text{min}} \end{pmatrix} = \begin{pmatrix} 6 & 0 \\ 0 & 2 \end{pmatrix}$$
.

 $\bullet$   $v_{\text{max}}$  ( $v_{\text{min}}$ ) direction of highest (lowest) curvature

**Proof:** With  $\mathbf{v} = \mathbf{V}^T \mathbf{x}$ :

$$\mathbf{x}^T \mathbf{A} \mathbf{x} = \mathbf{x}^T \mathbf{V} \wedge \mathbf{V}^T \mathbf{x} = \mathbf{v}^T \wedge \mathbf{v} = \sum_{i=1}^d \lambda_i v_i^2 \le \lambda_{\max} \sum_{i=1}^d v_i^2 = \lambda_{\max} \|\mathbf{v}\|^2$$

Since 
$$\|\mathbf{v}\| = \|\mathbf{x}\|$$
 (V orthogonal):  $\max_{\|\mathbf{x}\|=1} \mathbf{x}^T \mathbf{A} \mathbf{x} \leq \lambda_{\max}$  Additional:  $\mathbf{v}_{\max}^T \mathbf{A} \mathbf{v}_{\max} = \mathbf{e}_1^T \Lambda \mathbf{e}_1 = \lambda_{\max}$  Analogous:  $\min_{\|\mathbf{x}\|=1} \mathbf{x}^T \mathbf{A} \mathbf{x} \geq \lambda_{\min}$  and  $\mathbf{v}_{\min}^T \mathbf{A} \mathbf{v}_{\min} = \lambda_{\min}$ 

•  $v_{\text{max}}, v_{\text{min}}$  principal axes of contour ellipses (principal axis theorem)

**Proof:** With 
$$\mathbf{v} = \mathbf{V}^T \mathbf{x}$$
:

$$q(\mathbf{x}) = \mathbf{x}^{\mathsf{T}} \mathbf{A} \mathbf{x} + \mathbf{b}^{\mathsf{T}} \mathbf{x} + c = \mathbf{v}^{\mathsf{T}} \Lambda \mathbf{v} + \mathbf{b}^{\mathsf{T}} V \mathbf{v} + c =: \tilde{q}(\mathbf{v})$$

Now:

$$q(\mathbf{v}_i) = \mathbf{e}_i^T \Lambda \mathbf{e}_i + \mathbf{b}^T V \mathbf{e}_i + c = \tilde{q}(\mathbf{e}_i)$$

Especially: 
$$q(\mathbf{v}_{\text{max}}) = \lambda_{\text{max}} = \tilde{q}(\mathbf{e}_1)$$
 and  $q(\mathbf{v}_{\text{min}}) = \lambda_{\text{min}} = \tilde{q}(\mathbf{e}_d)$ 

Recall: Second order condition for optimality is sufficient.

We skipped the **proof** at first, but can now catch up on it.

If  $H(\mathbf{x}^*) \succ 0$  at stationary point  $\mathbf{x}^*$ , then  $\mathbf{x}^*$  is local minimum ( $\prec$  for maximum).

**Proof:** Let  $\lambda_{min} > 0$  denote the smallest eigenvalue of  $H(\mathbf{x}^*)$ . Then:

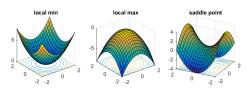

$$f(\mathbf{x}) = f(\mathbf{x}^*) + \underbrace{\nabla f(\mathbf{x}^*)}_{=0}^T (\mathbf{x} - \mathbf{x}^*) + \frac{1}{2} \underbrace{(\mathbf{x} - \mathbf{x}^*)^T H(\mathbf{x}^*)(\mathbf{x} - \mathbf{x}^*)}_{\geq \lambda_{\min} \|\mathbf{x} - \mathbf{x}^*\|^2 \text{ (see above)}} + \underbrace{R_2(\mathbf{x}, \mathbf{x}^*)}_{=o(\|\mathbf{x} - \mathbf{x}^*\|^2)}.$$

Choose  $\epsilon > 0$  s.t.  $|R_2(\mathbf{x}, \mathbf{x}^*)| < \frac{1}{2} \frac{\lambda_{\min}}{\|\mathbf{x} - \mathbf{x}^*\|^2}$  for each  $\mathbf{x}$  with  $\|\mathbf{x} - \mathbf{x}^*\| < \epsilon$ . Then:

$$f(\mathbf{x}) \ge f(\mathbf{x}^*) + \underbrace{\frac{1}{2} \frac{\lambda_{\min} \|\mathbf{x} - \mathbf{x}^*\|^2 + R_2(\mathbf{x}, \mathbf{x}^*)}_{>0}} > f(\mathbf{x}^*)$$
 for each  $\mathbf{x}$  with  $\|\mathbf{x} - \mathbf{x}^*\| < \epsilon$ .

If spectrum of  $\bf A$  is known, also that of  $\bf H=2A$  is known.

- If all eigenvalues of  $\mathbf{H} \overset{(>)}{\geq} \mathbf{0} \ (\Leftrightarrow \mathbf{H} \overset{(\succ)}{\succcurlyeq} \mathbf{0})$ :
  - q (strictly) convex,
  - there is a (unique) global minimum.
- If **all** eigenvalues of  $\mathbf{H} \overset{(<)}{\leq} 0 \ (\Leftrightarrow \mathbf{H} \overset{(\prec)}{\preccurlyeq} 0)$ :
  - q (strictly) concave,
  - there is a (unique) global maximum.
- If **H** has both positive and negative eigenvalues (⇔ **H** indefinite):
  - q neither convex nor concave,
  - there is a saddle point.

#### CONDITION AND CURVATURE

Condition of  $\mathbf{H}=2\mathbf{A}$  is given by  $\kappa(\mathbf{H})=\kappa(\mathbf{A})=|\lambda_{\max}|/|\lambda_{\min}|$ .

#### High condition means:

- $|\lambda_{\text{max}}| \gg |\lambda_{\text{min}}|$
- Curvature along v<sub>max</sub> ≫ curvature along v<sub>min</sub>
- Problem for optimization algorithms like gradient descent (later)

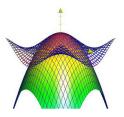

Left: Excellent condition. Middle: Good condition. Right: Bad condition.

#### APPROXIMATION OF SMOOTH FUNCTIONS

Any function  $f \in C^2$  can be locally approximated by a quadratic function via second order Taylor approximation:

$$f(\mathbf{x}) \approx f(\tilde{\mathbf{x}}) + \nabla f(\tilde{\mathbf{x}})^T (\mathbf{x} - \tilde{\mathbf{x}}) + \frac{1}{2} (\mathbf{x} - \tilde{\mathbf{x}})^T \nabla^2 f(\tilde{\mathbf{x}}) (\mathbf{x} - \tilde{\mathbf{x}})$$

f and its second order approximation is shown by the dark and bright grid, respectively. (Source: daniloroccatano.blog)

→ Hessians provide information about local geometry of a function.
