Optimization in Machine Learning Nonlinear programs and Lagrangian

Learning goals

- Lagrangian for general constrained optimization
- Geometric intuition for Lagrangian duality
- Properties and examples

NONLINEAR CONSTRAINED OPTIMIZATION

Previous lecture: Linear programs

$$egin{array}{ll} \min_{\mathbf{x} \in \mathbb{R}^d} & f(\mathbf{x}) := \mathbf{c}^{ op} \mathbf{x} \ & \mathbf{s.t.} & \mathbf{A} \mathbf{x} \leq \mathbf{b} \ & \mathbf{G} \mathbf{x} = \mathbf{h} \end{array}$$

Related to its (Lagrange) dual formulation by the Lagrangian

$$\mathcal{L}(\mathbf{x}, \alpha, \beta) = \mathbf{c}^{\top} \mathbf{x} + \alpha^{\top} (\mathbf{A} \mathbf{x} - \mathbf{b}) + \beta^{\top} (\mathbf{G} \mathbf{x} - \mathbf{h}).$$

Weak duality: For $\alpha \geq 0$ and β :

$$f(\mathbf{x}^*) \geq \min_{\mathbf{x} \in \mathcal{S}} \mathcal{L}(\mathbf{x}, \alpha, \beta) \geq \min_{\mathbf{x} \in \mathbb{R}^d} \mathcal{L}(\mathbf{x}, \alpha, \beta) =: g(\alpha, \beta)$$

Recall: Implicit domain constraint in *Lagrange dual function* $g(\alpha, \beta)$.

NONLINEAR CONSTRAINED OPTIMIZATION

General form of a constraint optimization problem

- Functions f, g_i , h_i generally nonlinear
- Transfer the Lagrangian from linear programs:

$$\mathcal{L}(\mathbf{x}, \boldsymbol{\alpha}, \boldsymbol{\beta}) := f(\mathbf{x}) + \sum_{i=1}^{k} \alpha_i g_i(\mathbf{x}) + \sum_{j=1}^{\ell} \beta_j h_j(\mathbf{x})$$

• Dual variables $\alpha_i \geq 0$ and β_i are also called *Lagrange multipliers*.

CONSTRAINED PROBLEMS: THE DIRECT WAY

Simple constrained problems can be solved in a direct way.

Example 1:

$$\min_{x \in \mathbb{R}} \quad 2 - x^2$$
s.t.
$$x - 1 = 0$$

Solution: Resolve the constraint by

$$x - 1 = 0$$
$$x = 1$$

and insert it into the objective:

$$x^* = 1, \quad f(x^*) = 1$$

CONSTRAINED PROBLEMS: THE DIRECT WAY

Example 2:

$$\min_{\mathbf{x} \in \mathbb{R}^2} \quad -2 + x_1^2 + 2x_2^2
\text{s.t.} \quad x_1^2 + x_2^2 - 1 = 0$$

Solution: Resolve the constraint

$$x_1^2 = 1 - x_2^2$$

and insert it into the objective

$$f(x_1, x_2) = -2 + (1 - x_2^2) + 2x_2^2$$

= -1 + x₂².

 \Rightarrow Minimum at $\mathbf{x}^* = (\pm 1, 0)^{\top}$. However, direct way mostly not possible.

Question 1: Is there a general recipe for solving general constrained nonlinear optimization problems?

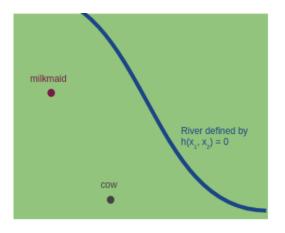

Question 2: Can we understand this recipe geometrically?

Question 3: How does this relate to the Lagrange function approach?

For this purpose, we consider the classical "milkmaid problem"; the following example is taken from *Steuard Jensen, An Introduction to Lagrange Multipliers* (but the example works of course equally well with a "milk man").

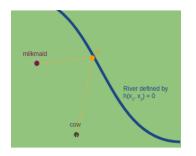

- Assume a milk maid is sent to the field to get the day's milk
- The milkmaid wants to finish her job as quickly as possible
- However, she has to clean her bucket first at the nearby river.

Where is the best point *P* to clean her bucket?

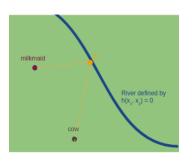

Aim: Find point P at the river for minimum total distance f(P)

- f(P) := d(M, P) + d(P, C) (d measures distance)
- h(P) = 0 describes the river

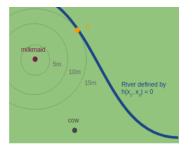

Corresponding optimization problem:

$$\min_{x_1, x_2} f(x_1, x_2)$$
s.t. $h(x_1, x_2) = 0$

Question: How far can the milkmaid get for a fixed total distance f(P)?

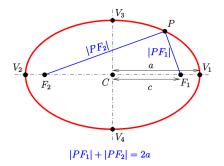

Assume: We only care about d(M, P).

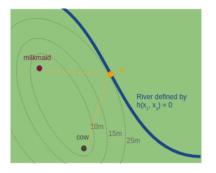

Observe: Radius of circle touching river first is the minimal distance.

- For f(P) = d(M, P) + d(P, C): Use an **ellipse**.
- **Def.:** Given two focal points F_1 , F_2 and distance 2a:

$$E = \{P \in \mathbb{R}^2 \mid d(F_1, P) + d(P, F_2) = 2a\}$$

- Let *M* and *C* be focal points of a collection of ellipses
- Find **smallest** ellipse touching the river $h(x_1, x_2)$
- Define P as the touching point

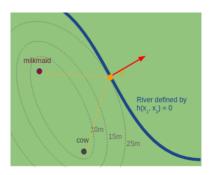

Question: How can we make sense of this mathematically?

- Recall: Gradient is normal (perpendicular) to contour lines
- Since contour lines of f and h touch, gradients are parallel:

$$\nabla f(P) = \beta \nabla h(P)$$

• Multiplier β is called **Lagrange multiplier**.

LAGRANGE FUNCTION

General: Solve problem with single equality constraint by:

$$\nabla f(\mathbf{x}) = \beta \nabla h(\mathbf{x})$$
$$h(\mathbf{x}) = 0$$

• First line: Parallel gradients | Second line: Constraint

Observe: Above system is equivalent to

$$\nabla \mathcal{L}(\mathbf{x}, \beta) = \mathbf{0}$$

for Lagrange function (or Lagrangian) $\mathcal{L}(\mathbf{x}, \beta) := f(\mathbf{x}) + \beta h(\mathbf{x})$

Indeed:

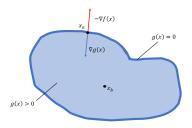

$$\begin{pmatrix} \nabla_{\mathbf{x}} \mathcal{L}(\mathbf{x}, \beta) \\ \nabla_{\beta} \mathcal{L}(\mathbf{x}, \beta) \end{pmatrix} = \begin{pmatrix} \nabla f(\mathbf{x}) + \beta \nabla h(\mathbf{x}) \\ h(\mathbf{x}) \end{pmatrix}$$

LAGRANGE FUNCTION

Idea can be extended to **inequality** constraints $g(\mathbf{x}) \leq 0$.

There are two possible cases for a solution:

- Solution \mathbf{x}_b inside feasible set: constraint is inactive ($\alpha_b = 0$)
- Solution \mathbf{x}_a on boundary $g(\mathbf{x}) = 0$: $\nabla f(\mathbf{x}_a) = \alpha_a \nabla g(\mathbf{x}_a)$ ($\alpha_a > 0$)

LAGRANGE FUNCTION AND PRIMAL PROBLEM

General constrained optimization problems:

$$\min_{\mathbf{x}} f(\mathbf{x})$$
s.t. $g_i(\mathbf{x}) \le 0, \quad i = 1, ..., k$

$$h_j(\mathbf{x}) = 0, \quad j = 1, ..., \ell$$

Extend Lagrangian ($\alpha_i \ge 0$, β_i Lagrange multipliers):

$$\mathcal{L}(\mathbf{x}, \boldsymbol{\alpha}, \boldsymbol{\beta}) := f(\mathbf{x}) + \sum_{i=1}^{k} \alpha_i g_i(\mathbf{x}) + \sum_{j=1}^{\ell} \beta_j h_j(\mathbf{x})$$

Equivalent primal problem:

$$\min_{\mathbf{x}} \max_{\alpha > 0.\beta} \mathcal{L}(\mathbf{x}, \alpha, \beta)$$

Question: Why?

LAGRANGE FUNCTION AND PRIMAL PROBLEM

For simplicity: Consider only single inequality constraint $g(\mathbf{x}) \leq 0$

If **x breaks** inequality constraint ($g(\mathbf{x}) > 0$):

$$\max_{\alpha \geq 0} \mathcal{L}(\mathbf{x}, \alpha) = \max_{\alpha \geq 0} f(\mathbf{x}) + \alpha g(\mathbf{x}) = \infty$$

If **x satisfies** inequality constraint $(g(\mathbf{x}) \leq 0)$:

$$\max_{\alpha \geq 0} \mathcal{L}(\mathbf{x}, \alpha) = \max_{\alpha \geq 0} f(\mathbf{x}) + \alpha g(\mathbf{x}) = f(\mathbf{x})$$

Combining yields original formulation:

$$\min_{\mathbf{x}} \max_{\alpha \geq 0} \mathcal{L}(\mathbf{x}, \alpha) = \begin{cases} \infty & \text{if } g(\mathbf{x}) > 0 \\ \min_{\mathbf{x}} f(\mathbf{x}) & \text{if } g(\mathbf{x}) \leq 0 \end{cases}$$

Similar argument holds for equality constraints $h_i(\mathbf{x})$

EXAMPLE: LAGRANGE FUNCTION FOR QP'S

We consider quadratic programming

$$\min_{\mathbf{x}} f(\mathbf{x}) := \frac{1}{2} \mathbf{x}^{\mathsf{T}} \mathbf{Q} \mathbf{x}$$
s.t. $h(\mathbf{x}) := \mathbf{C} \mathbf{x} - \mathbf{d} = \mathbf{0}$

with $\mathbf{Q} \in \mathbb{R}^{d \times d}$ symmetric, $\mathbf{C} \in \mathbb{R}^{\ell \times d}$, and $\mathbf{d} \in \mathbb{R}^{\ell}$.

Lagrange function: $\mathcal{L}(\mathbf{x}, \boldsymbol{\beta}) = \frac{1}{2}\mathbf{x}^{\top}\mathbf{Q}\mathbf{x} + \boldsymbol{\beta}^{\top}(\mathbf{C}\mathbf{x} - \mathbf{d})$

Solve

$$egin{aligned}
abla \mathcal{L}(\mathbf{x},oldsymbol{eta}) &= egin{pmatrix} \partial \mathcal{L}/\partial \mathbf{x} \ \partial \mathcal{L}/\partial oldsymbol{eta} \end{pmatrix} = egin{pmatrix} \mathbf{Q}\mathbf{x} + \mathbf{C}^{ op} oldsymbol{eta} \ \mathbf{C}\mathbf{x} - \mathbf{d} \end{pmatrix} = \mathbf{0} \ egin{pmatrix} \mathbf{Q} & \mathbf{C}^{ op} \ \mathbf{C} & \mathbf{0} \end{pmatrix} egin{pmatrix} \mathbf{x} \ oldsymbol{eta} \end{pmatrix} = egin{pmatrix} \mathbf{0} \ \mathbf{d} \end{pmatrix} \end{aligned}$$

Observe: Solve QP by solving a linear system

LAGRANGE DUALITY

Dual problem:

$$\max_{\boldsymbol{\alpha} \geq \mathbf{0}, \boldsymbol{\beta}} \min_{\mathbf{x}} \mathcal{L}(\mathbf{x}, \boldsymbol{\alpha}, \boldsymbol{\beta})$$

Define Lagrange dual function $g(\alpha, \beta) := \min_{\mathbf{x}} \mathcal{L}(\mathbf{x}, \alpha, \beta)$

Important characteristics of the dual problem:

- Convexity (pointwise minimum of affine functions)
 - Gives methods based on dual solutions
 - Might be computationally inefficient (expensive minimizations)
- Weak duality:

$$f(\mathbf{x}^*) \geq g(\alpha^*, \beta^*)$$

• Strong duality if primal problem satisfies Slater's condition⁽¹⁾:

$$f(\mathbf{x}^*) = g(\alpha^*, \boldsymbol{\beta}^*)$$

(1) Slater's condition: Primal problem convex and "strictly feasible" $(\exists \mathbf{x} \forall i : g_i(\mathbf{x}) < 0)$.
