# **Optimization**

# **Hessian Matrix & Taylor Series**

#### Learning goals

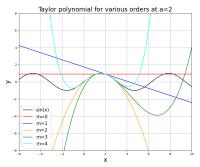

- Taylor series (Univariate)
- Hessian Matrix
- Taylor series (Multivariate)

# **DEFINITION TAYLOR'S THEOREM (UNIVARIATE)**

Let  $I \subseteq \mathbb{R}$  an open interval and  $a, x \in I$  and  $f \in \mathcal{C}^{m+1}(I, \mathbb{R})$ . Then

$$f(x) = T_m(x, a) + R_m(x, a)$$
, with

- *m*-th Taylor polynomial:  $T_m(x,a) \stackrel{(*)}{=} \sum_{k=0}^m \frac{f^{(k)}(a)}{k!} (x-a)^k$
- Remainder term:  $R_m(x, a)$  (we will cover this term later)

(\*) 
$$T_m(x,a) = f(a) + f'(a)(x-a) + \frac{f''(a)}{2!}(x-a)^2 + ... + \frac{f^{(m)}(a)}{m!}(x-a)^m$$

#### **DEFINITION HESSIAN MATRIX**

The 2nd derivative of a multivariate function  $f \in \mathcal{C}^2(\mathcal{S}, \mathbb{R})$ ,  $\mathcal{S} \subseteq \mathbb{R}^d$  (if it exists) is defined by the **Hessian** matrix

$$H(\mathbf{x}) = \nabla^2 f(\mathbf{x}) = \left(\frac{\partial^2 f(\mathbf{x})}{\partial x_i \partial x_j}\right)_{i,j=1...d}$$

**Example**: Let  $f(x_1, x_2) = sin(x_1) \cdot cos(x_2)$ . Then:

$$H(\mathbf{x}) = \begin{pmatrix} -\cos(x_2) \cdot \sin(x_1) & -\cos(x_1) \cdot \cos(x_2) \\ -\cos(x_1) \cdot \sin(x_2) & -\cos(x_2) \cdot \sin(x_1) \end{pmatrix}$$

### HESSIAN DESCRIBES LOCAL CURVATURE

Let w.l.o.g.  $A(\mathbf{x}) = \{\lambda_{1,\mathbf{x}},...,\lambda_{d,\mathbf{x}}\}$  be Eigenspectrum with  $\lambda_{1,\mathbf{x}} \leq \lambda_{2,\mathbf{x}} \leq ... \leq \lambda_{d,\mathbf{x}}$  of  $H(\mathbf{x})$ ; let  $\mathbf{v}_{i,\mathbf{x}}$  define the respective Eigenvectors. We can read from it:

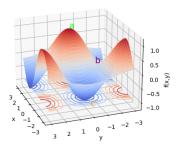

•  $v_d/v_1$  points in the direction of largest/smallest curvature

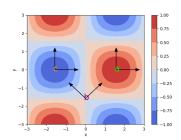

**Example (continued):** 
$$H(\mathbf{x}) = \begin{pmatrix} -\cos(x_2) \cdot \sin(x_1) & -\cos(x_1) \cdot \sin(x_2) \\ -\cos(x_1) \cdot \sin(x_2) & -\cos(x_2) \cdot \sin(x_1) \end{pmatrix}$$
.

• 
$$H(a)$$
,  $a = (\frac{\pi}{2}, 0)$ :  $\lambda_{1,a} = \lambda_{2,a} = -1$ ;  $v_{1,a} = (0, 1)^{\top}$ ,  $v_{2,a} = (1, 0)^{\top}$ 

• 
$$H(b)$$
,  $b = (0, \frac{-\pi}{2})$ :  $\lambda_{1,b} = -1$ ,  $\lambda_{2,b} = 1$ ;  $v_{1,b} = (-1,1)^{\top}$ ,  $v_{2,b} = (1,1)^{\top}$ 

• 
$$H(c), c = (\frac{-\pi}{2}, 0), : \lambda_{1,c} = \lambda_{2,c} = 1; v_{1,c} = (0,1)^{\top}, v_{2,c} = (1,0)^{\top}$$

#### REMAINDER TERM

$$f(x) = T_m(x, a) + R_m(x, a)$$

How close is  $T_m(x, a)$  to f(x)?

• Exact representation of  $R_m(x, a)$ :

$$R_m(x,a) := \int_a^x \frac{f^{(k+1)}(t)}{k!} (x-t)^k dt$$

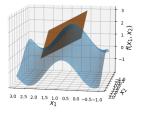

(integral form of remainder; alternative formulas exist, but are not covered here.)

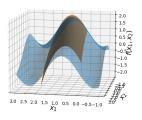

• In order of magnitude:

$$R_m(\mathbf{a}) \in \mathcal{O}(\|\mathbf{x} - \mathbf{a}\|^m)$$
 for  $\mathbf{x} \to \mathbf{a}$ 

#### REMAINDER TERM

- Higher *m* gives a better approximation
- The  $m^{th}$  order taylor series is the best  $m^{th}$  order approximation to  $f(\mathbf{x})$  near  $\mathbf{a}$

Consider  $T_2(\mathbf{x}, \mathbf{a}) = f(\mathbf{a}) + \nabla f(\mathbf{a})^{\top} (\mathbf{x} - \mathbf{a}) + \frac{1}{2} (\mathbf{x} - \mathbf{a})^{\top} H(\mathbf{a}) (\mathbf{x} - \mathbf{a})$ . The first term ensures the **value** of  $T_2$  and f match at  $\mathbf{a}$ . The second term ensures the **slopes** of  $T_2$  and f match at  $\mathbf{a}$ . The third term ensures the **curvature** of  $T_2$  and f match at  $\mathbf{a}$ .

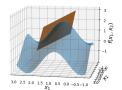

Bernd Bischl <sup>©</sup> Optimization − 5 / 9

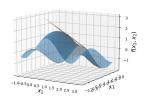

Taylor's theorem (1st order):

$$f(\mathbf{x}) = \underbrace{f(\mathbf{a}) + \nabla f(\mathbf{a})^{\top} (\mathbf{x} - \mathbf{a})}_{T_1(\mathbf{x}, \mathbf{a})} + R_1(\mathbf{x}, \mathbf{a})$$

**Example:** 
$$f(\mathbf{x}) = \sin(2x_1) + \cos(x_2), \ \mathbf{a} = (1, 1)^{\top}. \text{ Since } \nabla f(\mathbf{x}) = \begin{pmatrix} 2 \cdot \cos(2x_1) \\ -\sin(x_2) \end{pmatrix}$$

$$f(\mathbf{x}) = T_1(\mathbf{x}) + R_1(\mathbf{x}, \mathbf{a}) = f(\mathbf{a}) + \nabla f(\mathbf{a})^{\top} (\mathbf{x} - \mathbf{a}) + R_1(\mathbf{x}, \mathbf{a})$$
$$= \sin(2) + \cos(2) + (2 \cdot \cos(2), -\sin(1)) \begin{pmatrix} x_1 - 1 \\ x_2 - 1 \end{pmatrix} + R_1(\mathbf{x}, \mathbf{a})$$

Bernd Bischl © Optimization - 6 / 9

Taylor's theorem (2nd order):

$$f(\mathbf{x}) = \underbrace{f(\mathbf{a}) + \nabla f(\mathbf{a})^{\top} (\mathbf{x} - \mathbf{a}) + \frac{1}{2} (\mathbf{x} - \mathbf{a})^{\top} H(\mathbf{a}) (\mathbf{x} - \mathbf{a})}_{T_2(\mathbf{x}, \mathbf{a})} + R_2(\mathbf{x}, \mathbf{a})$$

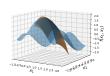

**Example (continued):**  $f(\mathbf{x}) = \sin(2x_1) + \cos(x_2)$ ,  $\mathbf{a} = (1, 1)^{\mathsf{T}}$ . Since

$$\nabla f(\mathbf{x}) = \begin{pmatrix} 2 \cdot \cos(2x_1) \\ -\sin(x_2) \end{pmatrix} \text{ and } H(\mathbf{x}) = \begin{pmatrix} -4\sin(2x_1) & 0 \\ 0 & -\cos(x_2) \end{pmatrix}$$

we get

$$f(\mathbf{x}) = T_1(\mathbf{x}, \mathbf{a}) + \frac{1}{2} \begin{pmatrix} x_1 - 1 \\ x_2 - 1 \end{pmatrix}^{\top} \begin{pmatrix} -4\sin(2) & 0 \\ 0 & -\cos(1) \end{pmatrix} \begin{pmatrix} x_1 - 1 \\ x_2 - 1 \end{pmatrix} + R_2(\mathbf{x}, \mathbf{a})$$

Bernd Bischl <sup>©</sup> Optimization − 7/9

What can be written down nicely for first and second order Taylor Series is (notationally) a bit more cumbersome for general k.

Let  $f: \mathbb{R}^d \to \mathbb{R}$ ,  $f \in \mathcal{C}^k$  at  $\boldsymbol{a} \in \mathbb{R}^d$ . Then

$$f(x) = T_m(\mathbf{x}, \mathbf{a}) + R_m(\mathbf{x}, \mathbf{a}), \text{ with }$$

$$T_m(\mathbf{x}, \mathbf{a}) = \sum_{|\alpha| \le k} \frac{D^{\alpha} f(\mathbf{a})}{\alpha!} (\mathbf{x} - \mathbf{a})^{\alpha} \text{ and } \lim_{\mathbf{x} \to \mathbf{a}} R_m(\mathbf{x}, \mathbf{a}) = 0$$

with  $lpha \in \mathbb{N}^d$  and the multi-index notation

- $\bullet |\alpha| = \alpha_1 + \cdots + \alpha_d$
- $\alpha! = \alpha_1! \cdots \alpha_d!$
- $\bullet \ \mathbf{x}^{\alpha} = \mathbf{x}_1^{\alpha_1} \cdots \mathbf{x}_d^{\alpha_d}$
- $D^{\alpha}f = \frac{\partial^{|\alpha|}f}{\partial x_1^{\alpha_1} \cdots \partial x_d^{\alpha_d}}$

Let's check for  $f: \mathbb{R}^2 \to \mathbb{R}$  and k = 1. We have for  $|\alpha| < 1$ :

• 
$$\alpha_1 = 0, \alpha_2 = 0$$
:  $|\alpha| = 0, \alpha! = 1, \mathbf{x}^{\alpha} = 1, D^{\alpha}f = 1$ 

• 
$$\alpha_1 = 1, \alpha_2 = 0$$
:  $|\alpha| = 1, \alpha! = 1, \mathbf{x}^{\alpha} = x_1, D^{\alpha} f = \frac{\partial f}{\partial x_1}$ 

• 
$$\alpha_1 = 0, \alpha_2 = 1$$
:  $|\alpha| = 1, \alpha! = 1, \mathbf{x}^{\alpha} = x_2, D^{\alpha} f = \frac{\partial f}{\partial x_2}$ 

and therefore:

$$T_{m}(\mathbf{x}, \mathbf{a}) = \sum_{|\alpha| \leq k} \frac{D^{\alpha} f(\mathbf{a})}{\alpha!} (\mathbf{x} - \mathbf{a})^{\alpha}$$

$$= \frac{1 \cdot f(\mathbf{a})}{1} \cdot 1 + \frac{\partial f}{\partial x_{1}} (\mathbf{a}) (x_{1} - a_{1}) + \frac{\partial f}{\partial x_{2}} (\mathbf{a}) (x_{2} - a_{2})$$

$$= f(\mathbf{a}) + \begin{pmatrix} \frac{\partial f}{\partial x_{1}} (\mathbf{a}) \\ \frac{\partial f}{\partial x_{2}} (\mathbf{a}) \end{pmatrix}^{\top} \begin{pmatrix} x_{1} - a_{1} \\ x_{2} - a_{2} \end{pmatrix} = f(\mathbf{a}) + \nabla f(\mathbf{a})^{\top} (\mathbf{x} - \mathbf{a}).$$
